Programming Assingment 1: Singular Value Decomposition Applications

Due on March 4 @ 4:00pm

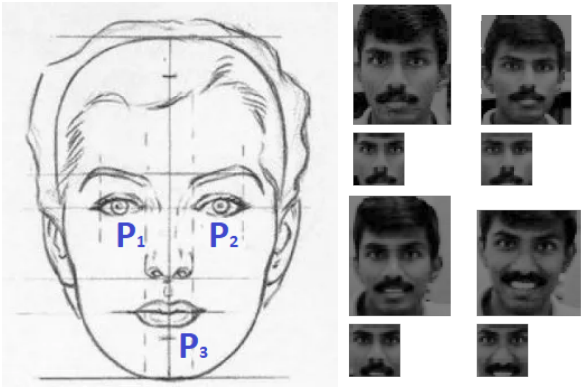
CS 685/485 – Computer Vision

Contents

Problem 1 2
Problem 2 4

Problem 1

[100 pts] Most face recognition algorithms require that human faces in an image be normalized prior to recognition. In general, normalization is performed with respect to location, size, orientation, and lighting. Here, you would need to implement a simple algorithm based on affine transformations. Specifically, the algorithm uses an affine transformation to map certain facial features to predetermined locations in a fixed window. Figure 1(a) shows an example of such facial features.



(a) (b)

Figure 1: (a) A sketch of a typical face. In this sketch the features of interest, e.g. the left eye, the right eye, and the center of the mouth, are selected. (b) Different face images may have different resolutions or come in different sizes. The first process is to normalize face images (the top image) into a uniform window size (the bottom image).

Figure 1(b) shows examples of faces normalized with respect to location, size, and orientation. A set of images to be used in your experiments is available from the assignment attachments. In this assignment, you will be using the following 4 facial features: left eye center, right eye center, nose tip and mouth center.

First, you will need to extract manually the actual coordinates of these facial features from each face image provided. Use any image viewer that shows the image coordinates for the location currently under the mouse cursor. Then, you have to choose the predetermined locations of these features in a fixed size window, say 48×40, and compute the parameters of the affine transformation. **Note:** the original images have size 112×92, so the aspect ratio is maintained.

Every feature point needs to be mapped to its predetermined location in the fixed window, thus it needs to satisfy the affine transformation equations. The example below considers only 3 features, although you will use 4. Denote the actual eye and mouth locations with (P_1, P_2, P_3) and their predetermined (fixed) locations with ($\hat{P}_1$, $\hat{P}_2$, $\hat{P}_3$). The affine transformation equations are given below:

$$\begin{aligned} \hat{P}_1 &= AP_1 + b \\ \hat{P}_2 &= AP_2 + b \\ \hat{P}_3 &= AP_3 + b \end{aligned} \tag{1}$$

where

$$A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \qquad b = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix} \tag{2}$$

The above equation can be rewritten as:

$$\begin{aligned} \hat{p}_x &= P \cdot c_1 \\ \hat{p}_y &= P \cdot c_2 \end{aligned} \tag{3}$$

Problem 1 continued on next page...

where

$$p_x = \begin{bmatrix} \hat{X}_1 \\ \hat{X}_2 \\ \hat{X}_3 \end{bmatrix} \qquad p_y = \begin{bmatrix} \hat{Y}_1 \\ \hat{Y}_2 \\ \hat{Y}_3 \end{bmatrix} \tag{4}$$

and

$$c_1 = \begin{bmatrix} a_{11} \\ a_{12} \\ b_1 \end{bmatrix} \qquad c_2 = \begin{bmatrix} a_{21} \\ a_{22} \\ b_2 \end{bmatrix} \tag{5}$$

and

$$P = \begin{bmatrix} X_1 & Y_1 & 1 \\ X_2 & Y_2 & 1 \\ X_3 & Y_3 & 1 \end{bmatrix} \tag{6}$$

Since each facial feature from each image contributes a pair of equations (one for the x coordinates and one for the y coordinates), by putting together all the equations for that image we obtain an over-determined set of linear equations that can be solved using Singular Value Decomposition (SVD). The code for solving over-determined systems of equations is available on the assignment attachments and as a functionality within OpenCV.

Once you have solved for the parameters of the affine transformation for each image, you have to normalize each image using its computed affine transformation.

Deliverables

a) An electronic (on Canvas) report describing your results. The report must include the following items:

- your approach, broken down in steps;
- recovered parameters for the affine transformations;
- the normalized images;
- a discussion of results and comparisons;
- you should verify how well the computed affine transformations align the actual facial features with the fixed ones (compute and report the average error in pixels) for all figures provide captions with a brief description.

b) One ZIP file containing the following:

- The source code files in C/C++. Make sure the source code is fully documented.
- A README file with instructions on how to compile and run the program and any parameters that need to be set.

Problem 2

[Graduate Students Only. Extra Credit for Undergrad Students -10pts] Once a face image has been normalized with respect to position, scale, and orientation, some lighting correction can be applied to account for non-uniform illumination. First, a linear (or higher order) model is fit to the intensity of the image; for example, the following model can be used:

$$f(x, y) = a \cdot x + b \cdot y + c \cdot xy + d \tag{7}$$

Each pixel (x, y) in the input image must satisfy the above equation where $f(x, y)$ is the intensity value of the input image at location (x, y). Using SVD, we can find the "best" coefficients a, b, c, and d (in a "least-squares" sense). For an $N \times M$ image, this yields NM equations with four unknowns (an over-determined system).

Figure 2: Original images (1st row), model fit (2nd row), lighting normalized images (3rd row).

Figure provides an example; the first row shows some input images while the second row shows the linear model fit to each of these images. To correct for lighting, simply subtract the linear model from the original image. The last row of Figure shows the results. Your task is to apply such lighting normalization on the normalized face images obtained in the previous problem.
